Final Steps Critical to Prosthetic Success

(Continued from page 3)

**Fitting & Alignment**

“Fit” refers to the quality of the interface between the socket and residual limb. “Alignment” is the important relationship of the socket, ankle and foot in a below-knee prosthesis (adding the knee for an above-knee limb). Because a unilateral lower-limb amputee expends an estimated 40 percent more energy walking than a person without limb loss, it is essential that the limb function with optimal efficiency.

Transparent check (or test) sockets can greatly enhance the ultimate socket fit, because they allow our prosthetic team to view the residual limb inside the socket while the patient is walking. Discovering areas of excessive pressure and less than total contact with a check socket enables prosthetists to make corrections throughout the fitting process and thereby reduce the risk of skin breakdown, pistoning, discomfort and-tear concerns can be accomplished.

**Follow-up & Maintenance**

Initially, after receiving their permanent prosthesis, new amputees usually return to their prostheterist frequently for adjustments and to pose questions that become evident as they gain endurance and “spread their wings.”

A few months after a return visit typically declines to once every 3-4 months. Follow-up visits address any problems the amputee may be having and routine maintenance, cleaning and replace-ment of mechanical and electronic components. Follow-up is a lifelong activity.

Our well qualified staff is prepared to escort amputees through the prosthetic process and help them achieve the ultimate functional outcome of which they are capable. We welcome your inquiries about any aspect of prosthetic care or management options for specific patients.

T

he diagnosis construction worker Kyle J., 38, received in mid-2008 was troubling: MRSA*, the antibiotic resistant staph infection that can be fatal, had developed in an open sore on his left foot and spread up his leg. By the time the Type II diabetes patient (already challenged by a prior mid-metatarsal amputation of his right foot) obtained appropriate treatment, the infection was out of control, leading ultimately to transfibial removal of his left leg.

Kyle’s amputation and course of rehabilitation provide an excellent illustration of the process a new amputee follows from limb removal surgery to a successful return to ambulatory mobility.

Not all amputees achieve prosthetic success, of course: Many factors can limit their amputation potential and motivation—age, poor health, lack of vitality and various psychological factors, among others.

However, those who successfully resume their pre-limb-loss lifestyle begin before amputation with the prosthetist involved, (usually the amputee’s personal physician, the amputating surgeon and sometimes a physical therapist), a physical and/or occupational therapist, perhaps a nurse and/or social worker, and of course, a well-qualified prosthetist. This article reviews the typical milestones a lower-limb amputee passes on the road to a successful prosthetic outcome.

Kyle awake from his surgery with a removable rigid dressing covering his amputation wound. A few days later, a prosthesis and foot were added, providing a platform for early weight-bearing and facilitating exercise. Before leaving the hospital, Kyle received initial physical therapy and a follow-up visit from his prosthetist, who would engineer his return to an ambulatory lifestyle.

**Referral & Initial Care**

In an ideal world, prosthetic intervention would begin before amputation with the prosthetist interacting with the patient to answer questions and relieve anxiety and taking part in discussions regarding amputation level, type of post-surgical dressing to be used, anticipated complications, and patient and family expectations. As a practical matter, such early involvement is often not feasible, and the prosthetist’s involvement begins a few—or many—days after limb removal.

Once amputation level is determined, an ensuing decision involves the type of dressing that will cover the wound, a choice that can have significant prosthetic implications.

The Prosthetic Process – Stepping Stones to Restored Mobility

Evaluation & Assessment

A comprehensive initial evaluation and assessment of a new amputee’s ambulation potential are key to a successful outcome and appropriate expenditure of health care resources. The prosthetist needs to know how well the residual limb will bear up under the stresses of weight-bearing and whether the patient’s overall state of health and other medical issues will limit him or her ability to use a prosthetic effectively.

For various reasons, including limited range of motion, generalized weakness, and inability to bear weight on the residual limb due to tarsal, shape and/or pain issues, this evaluation may reveal a new residual limb will receive relatively little benefit from a functional prosthesis.

In such instances a simple cosmetic device or no prosthesis at all is sometimes the most appropriate choice. At the opposite end of the spectrum are younger, otherwise healthy amputees who are candidates for sophisticated, high-capability replacement limbs.

During the initial visit with his prosthetist, Kyle was measured for his preambulatory (or “training”) prosthesis, a temporary leg he would use for several months while the size and shape of his residual limb stabilized and he learned to walk on a prosthetic limb. The preparatory limb, consisting of a custom socket, pylon and basic prosthetic foot, enabled him to continue gait training with his therapist, which had begun soon after surgery.

Over subsequent weeks, as his walking proficiency improved and his residual limb volume continued to decrease, Kyle revisited his prosthetist several times for socket modification and alignment adjustments—important steps along the road to optimizing his gait. Four months later, with his residual limb volume stabilized and his gait training progressing indicating he was nearing his goal of becoming a community ambulator, Kyle was ready to progress to his definitive limb.

Preparatory Phase

At its name suggests, the function of a preparatory prosthesis to help a new amputee transition to a new life of walking on an artificial limb. This is typically an adjustable system prosthetists can adapt to patients while they are learning a new way of walking and managing change in their residual limb. The preparatory prosthesis also helps the clinical team determine the amputee’s ultimate ambulation potential and the most appropriate components for the permanent system.

Vacuum forming a socket over mold

Check sockets enable prosthetist to view residual limb in “working” environment.

Starting with a cast impression of Kyle’s nearly mature residual limb, his prosthetist made appropriate modifications to ensure total contact, then fashioned a transparent check socket with which the degree of total contact and areas of undesirable pressure distribution could be visualized and corrected. After socket modification, the remaining components were attached and a cosmetic skin added to complete the prosthesis.

The Definitive Prosthesis

Selecting the most appropriate components for a new amputee’s specific needs and abilities is an essential part of the prosthetic process. After a careful preparatory phase, the definitive prosthesis is fabricated using more permanent materials and incorporating all knowledge gained to date.

Various factors must be weighed in making the prosthetic prescription:

• the condition and weight-bearing ability of the residual limb;
• the patient’s overall health, activity level, vocational needs and expectations;
• the type of suspension most appropriate for the amputee;
• specific components to be used, including socket, foot, pylon and (if applicable) knee unit;
• cosmetic finishing, and cost and funding.

Designing and building a prosthetic is an art, requiring knowledge, skill and experience. Traditionally, socket design and fabrication have been primarily manual procedures; however, CAD/CAM (computer-aided design/computer-aided manufacturing) systems are now increasingly being used to streamline the process.

Starting with information from a direct scan or negative cast of the residual limb, CAD/CAM software presents a visual image of the limb from which the prosthetist can design a socket on a monitor, optimizing the overall shape and trimlines and adding build-ups and reliefs as necessary. Finally, the CAD/CAM system feeds the design to a carver, which that creates a positive model over which the shell of the definitive socket can be vacuum-formed.

Once Kyle’s definitive limb was fabricated, the next step was fine-tuning the fit and alignment of the system to achieve optimal functional performance, comfort and safety. After ensuring the socket fit properly and testing the suspension, Kyle’s prosthetist evaluated the static alignment, noting the length and angulation of the prosthesis as Kyle stood upright and relaxed. Next came dynamic alignment involving careful analysis of Kyle’s gait and making adjustments to optimize function, maximize comfort and minimize energy expenditure.

From Amputation to Ambulation

The diagnosis construction worker Kyle J., 38, received in mid-2008 was troubling: MRSA*, the antibiotic-resistant staph infection that can be fatal, had developed in an open sore on his left foot and spread up his leg. By the time the Type II diabetes patient (already challenged by a prior mid-metatarsal amputation of his right foot) obtained appropriate treatment, the infection was out of control, leading ultimately to transfibial removal of his left leg.

Kyle’s amputation and course of rehabilitation provide an excellent illustration of the process a new amputee follows from limb removal surgery to a successful return to ambulatory mobility.

Not all amputees achieve prosthetic success, of course: Many factors can limit their amputation potential and motivation—age, poor health, lack of vitality and various psychological factors, among others. However, those who successfully resume their pre-limb-loss lifestyle do so after completing a well-defined process generally involving doctors (usually the amputee’s personal physician, the amputating surgeon and sometimes a physical therapist), a physical and/or occupational therapist, perhaps a nurse and/or social worker, and of course, a well-qualified prosthetist. This article reviews the typical milestones a lower-limb amputee passes on the road to a successful prosthetic outcome.

Kyle awoke from his surgery with a removable rigid dressing covering his amputation wound. A few days later, a pylon and prosthetic foot were added, providing a platform for early weight-bearing and facilitating exercise. Before leaving the hospital, Kyle received initial physical therapy and a follow-up visit from his prosthetist, who would engineer his return to an ambulatory lifestyle.

Fitting & Alignment

"Fit" refers to the quality of the interface between the socket and residual limb. "Alignment" is the important relationship of components in relation to the socket to provide the best-possible condition. The prosthetist adjusts the positioning of the lower-limb amputee expends an estimated 40 percent more energy walking than a person without limb loss, it is essential that the limb function with optimal efficiency.

Transparent check (or test) sockets can greatly enhance the ultimate socket fit, because they allow our prosthetic team to view the residual limb inside the socket while the patient is walking. Discovering areas of excessive pressure and less than total contact with a check socket enables prosthetists to make corrections throughout the fitting process and thereby reduce the risk of skin breakdown, pinching, discomfort and other problems that would likely limit the patient’s outcome.

Alignment is corrected as necessary in response to new components introduced or changes in physical condition. The prosthetist adjusts the positioning of the lower components in relation to the socket to provide the best possible balance, comfort, gait pattern, energy efficiency and cosmesis. Traditional mechanical methods are now being enhanced by advanced laser and digital equipment that bring new simplicity and precision to the alignment process. Once the alignment is completed, cosmetic finishing can be applied if desired, and the prosthetic leg is ready to go.

By the time Kyle received his definitive new leg, he was close to achieving his goal activities: to be able to wear his prosthetic leg for the better part of each day and to ambulate effectively at home and in the community. Though no longer able to perform rigorous construction functions, he has a good understanding of his limitations and is returning to school to learn a less physically demanding skill. Every few months, he will return for prosthetic follow-up visits, during which adjustments for further residual limb changes and wear-and-tear concerns can be accomplished.

Follow-up visits address any problems the amputee may be having and routine maintenance, cleaning and replacement of mechanical and electronic components. Follow-up is a lifelong activity.

Our well-qualified staff is prepared to escort amputees through the prosthetic process and help them achieve the ultimate functional outcome of which they are capable. We welcome your inquiries about any aspect of prosthetic care or management options for specific patients.
